ABSTRACT OF THE DISCLOSURE

Method of dissociating the extracellular haemoglobin molecule of annelids, e.g. Arenicola marina, which can be used to obtain the protein chains forming the molecule. The method includes a step of bringing an extracellular haemoglobin sample from annelids, e.g. Arenicola marina, into contact with at least one dissociating agent, e.g. a mixture containing dithiothreitol (DTT) or tris(2-carboxyethyl)phosphine (TCEP) hydrochloride or beta-mercaptoethanol and a dissociation buffer for a sufficient length of time in order to separate the protein chains from one another.
